

9-2 The Krebs Cycle and Electron Transport

9-2 The Krebs Cycle and Electron Transport

Oxygen is required for the final steps of cellular respiration.

Because the pathways of cellular respiration require oxygen, they are **aerobic**.

The Krebs Cycle

In the presence of oxygen, pyruvic acid produced in glycolysis passes to the second stage of cellular respiration, the **Krebs cycle**.

What happens during the Krebs cycle?

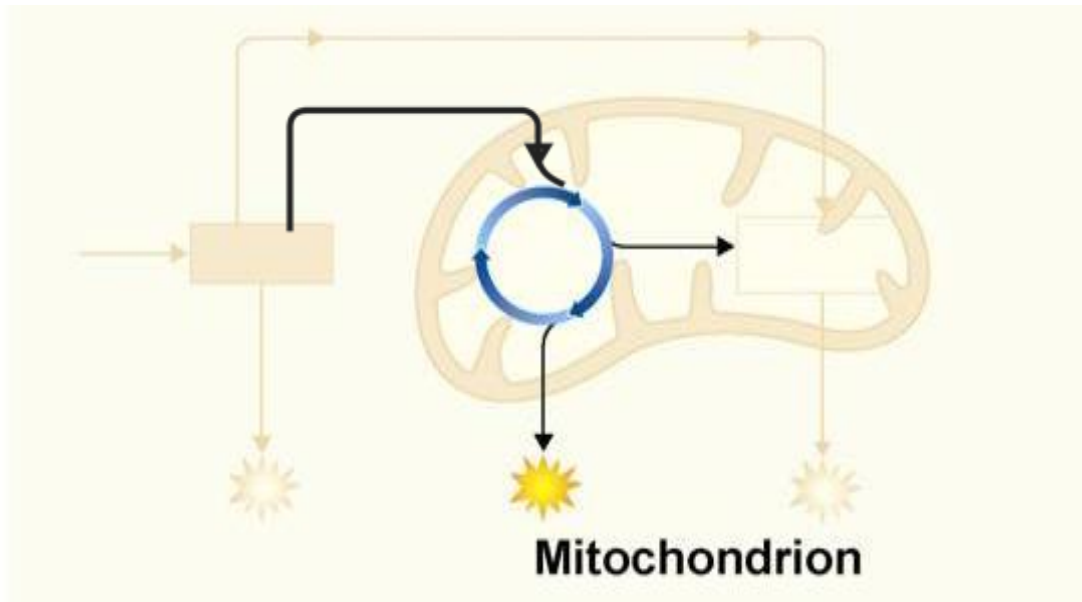

During the Krebs cycle, pyruvic acid is broken down into carbon dioxide in a series of energy-extracting reactions.

9-2 The Krebs Cycle and The Krebs Cycle Electron Transport

movie
click to start

 Pyruvic acid

The Krebs cycle begins when pyruvic acid produced by glycolysis enters the mitochondrion.

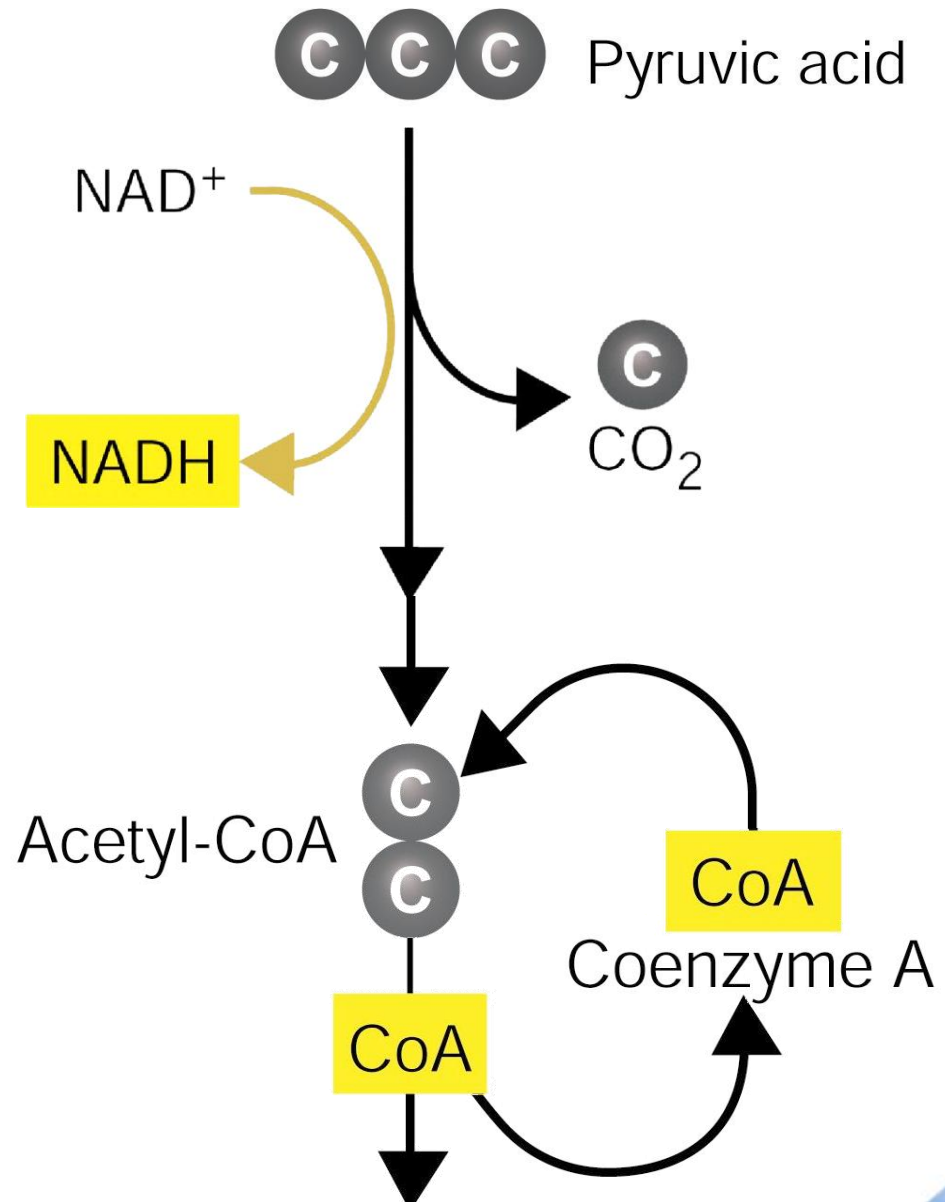

9-2 The Krebs Cycle and The Krebs Cycle Electron Transport

One carbon molecule is removed, forming CO_2 , and electrons are removed, changing NAD^+ to NADH .

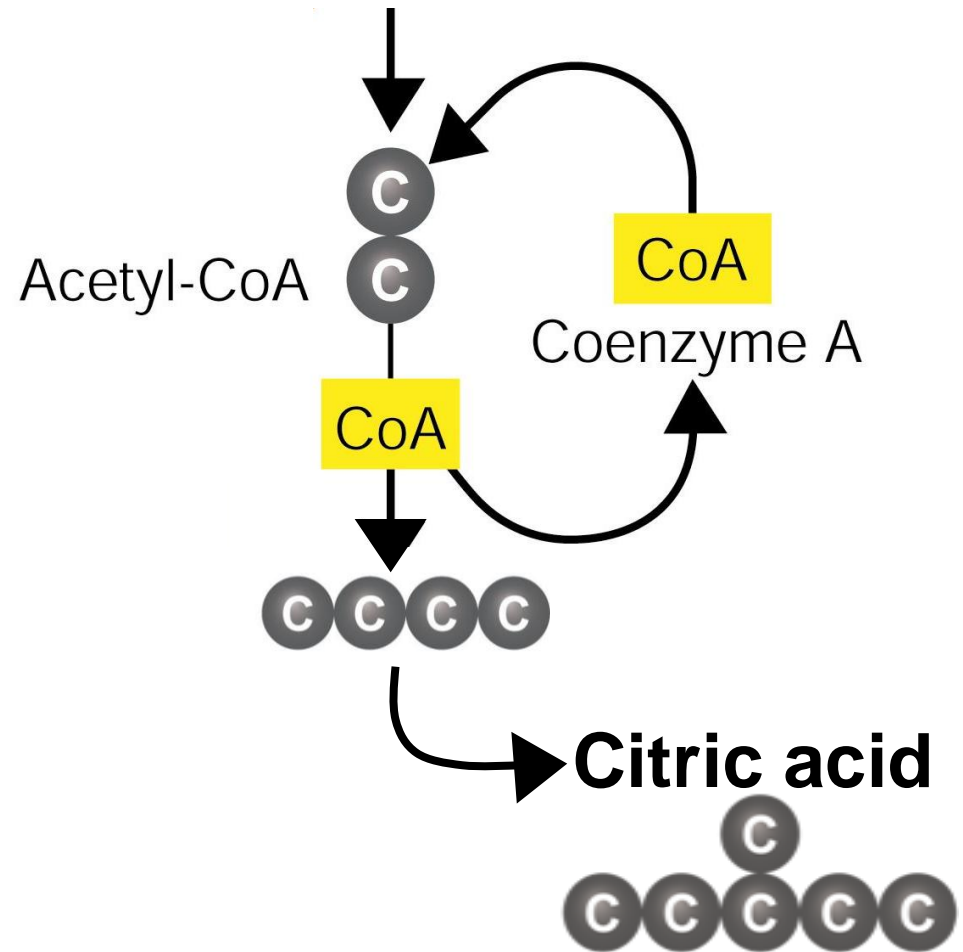

9-2 The Krebs Cycle and The Krebs Cycle Electron Transport

Coenzyme A joins the 2-carbon molecule, forming acetyl-CoA.

9-2 The Krebs Cycle and The Krebs Cycle Electron Transport

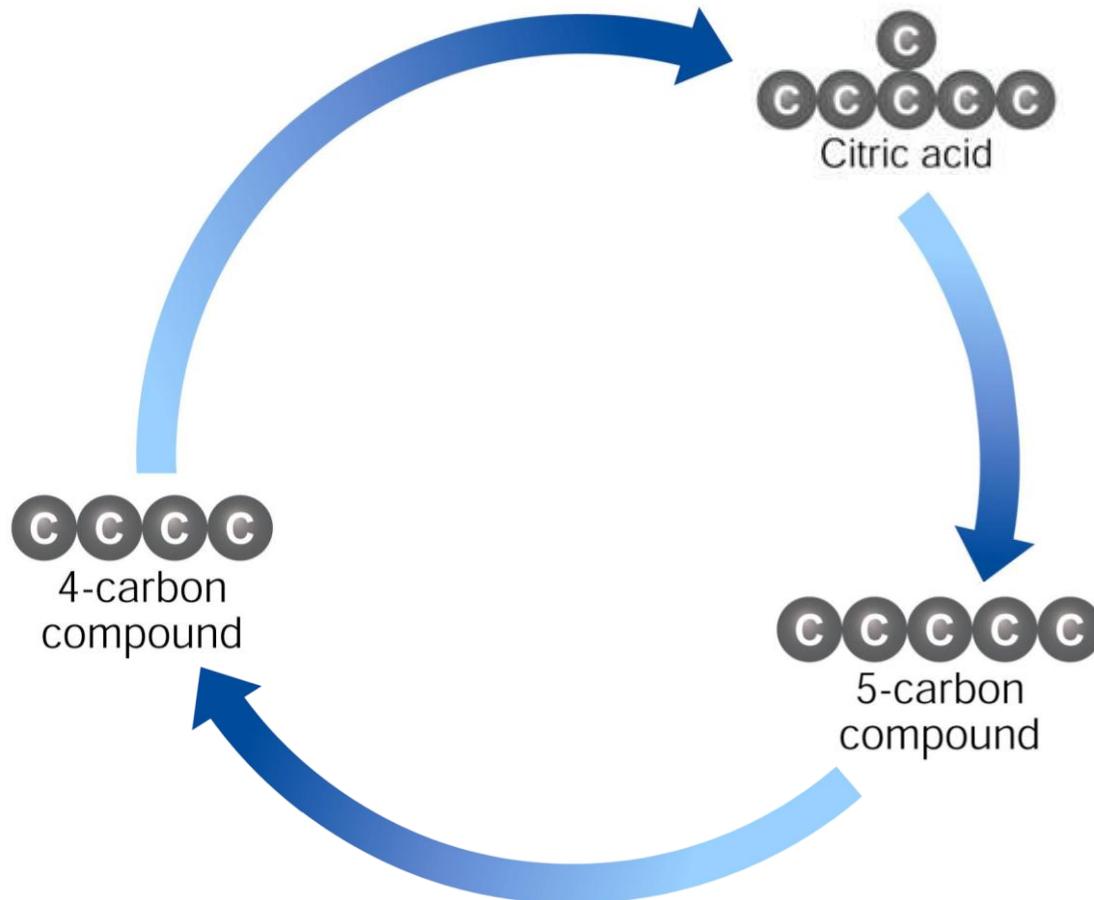

Acetyl-CoA then adds the 2-carbon acetyl group to a 4-carbon compound, forming citric acid.

9-2 The Krebs Cycle and The Krebs Cycle Electron Transport

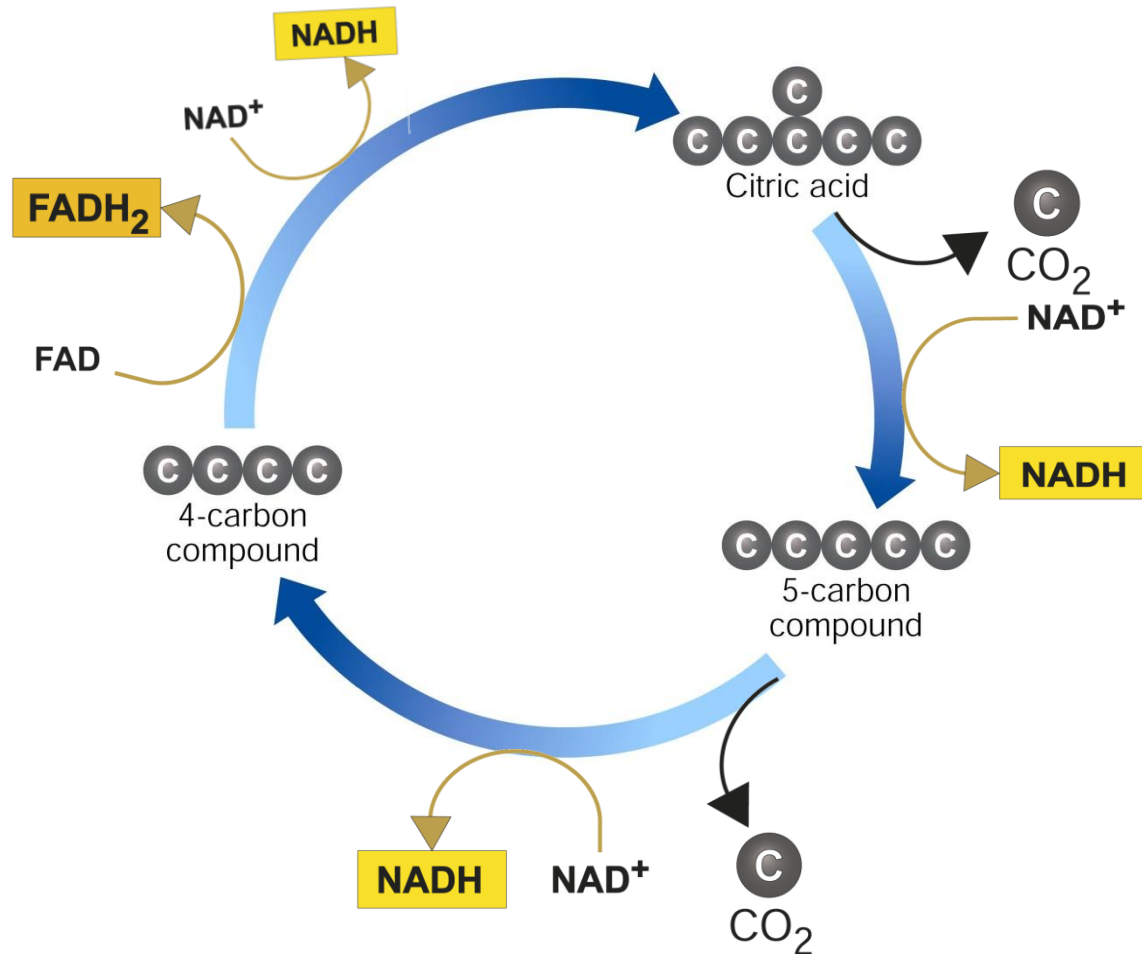

movie
click to start

Citric acid is broken down into a 5-carbon compound, then into a 4-carbon compound.

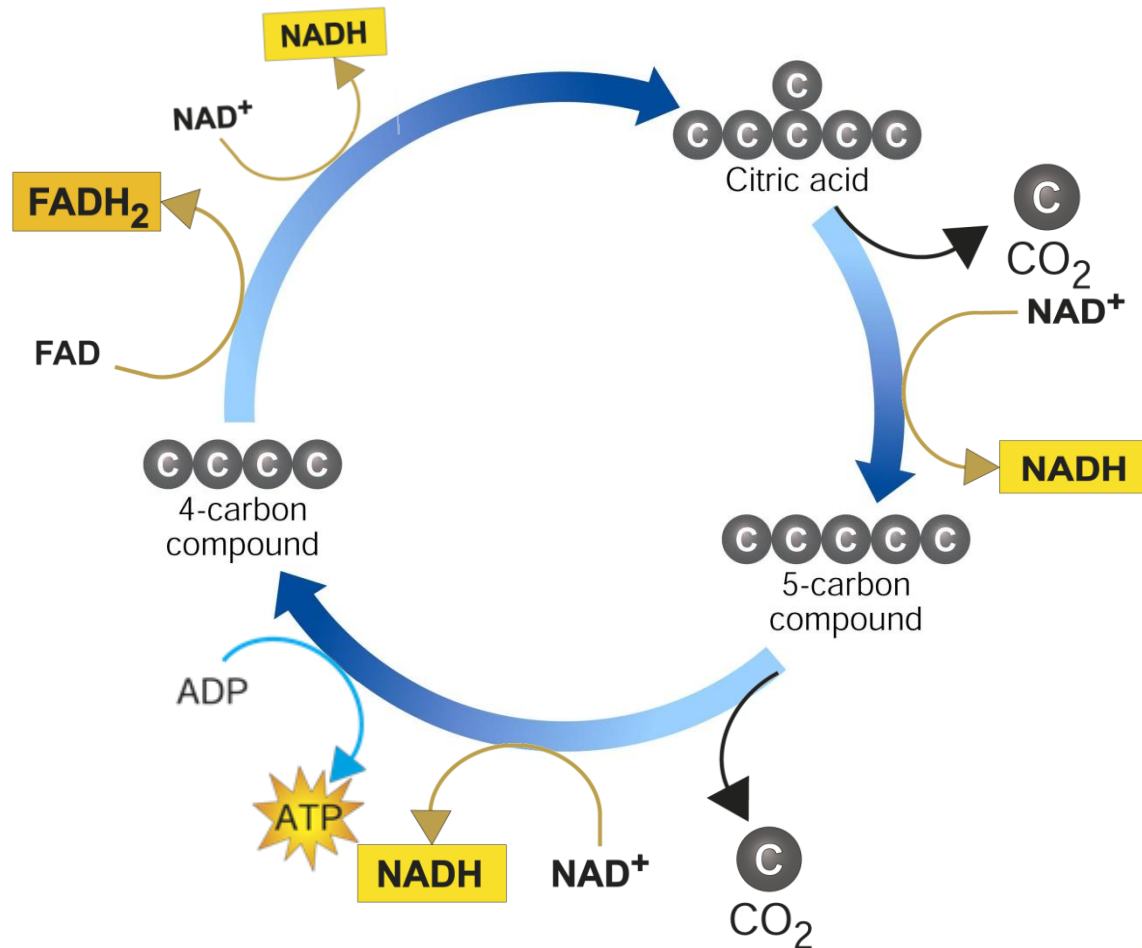

9-2 The Krebs Cycle and The Krebs Cycle Electron Transport

Two more molecules of CO_2 are released and electrons join NAD^+ and FAD , forming NADH and FADH_2 .

9-2 The Krebs Cycle and The Krebs Cycle Electron Transport

In addition, one molecule of ATP is generated.

9-2 The Krebs Cycle and The Krebs Cycle Electron Transport

The energy tally from 1 molecule of pyruvic acid is

- 4 NADH
- 1 FADH₂
- 1 ATP

9-2 The Krebs Cycle and The Krebs Cycle Electron Transport

What does the cell do with all those high-energy electrons in carriers like NADH?

In the presence of oxygen, those high-energy electrons can be used to generate huge amounts of ATP.

How are high-energy electrons used by the electron transport chain?

Electron Transport

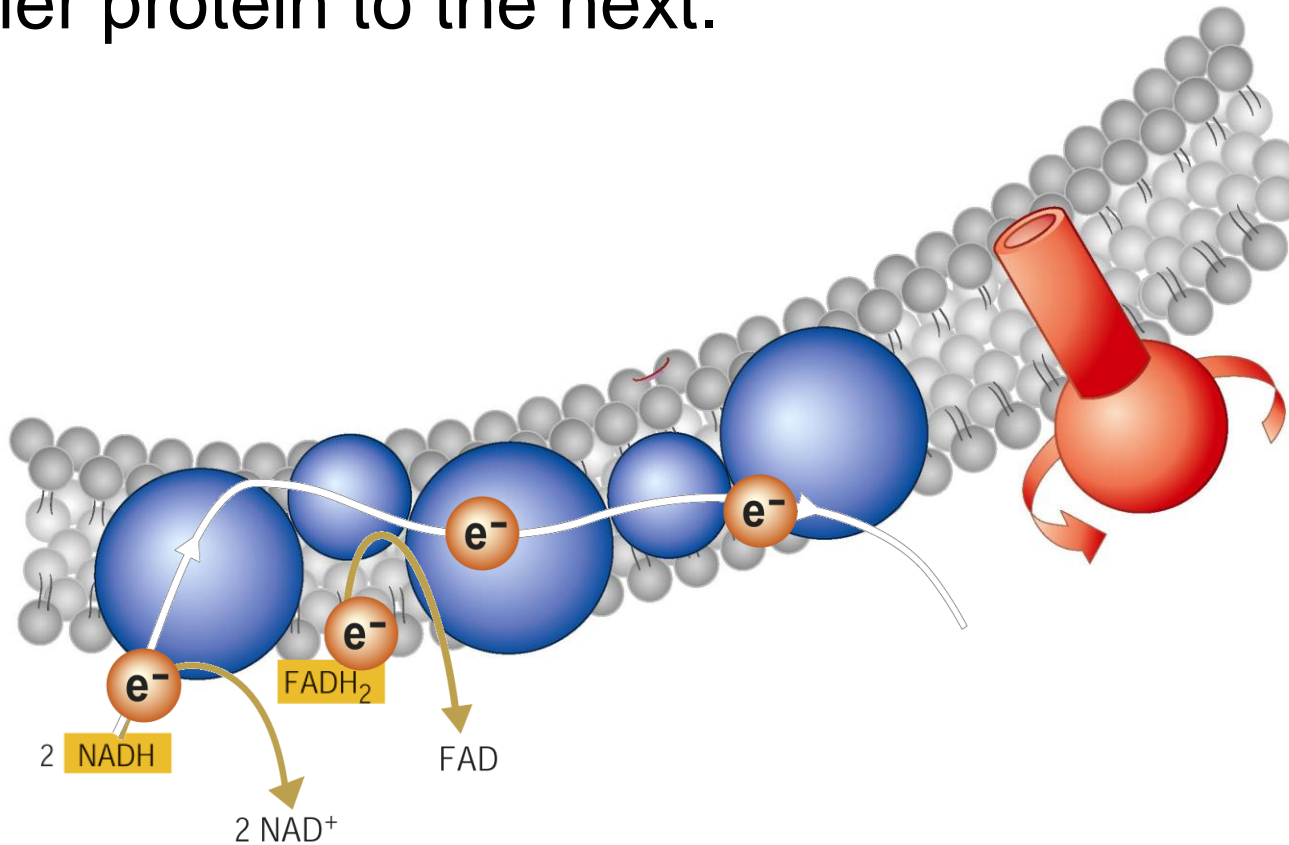

The electron transport chain uses the high-energy electrons from the Krebs cycle to convert ADP into ATP.

9-2 The Krebs Cycle and Electron Transport Electron Transport

movie
click to start

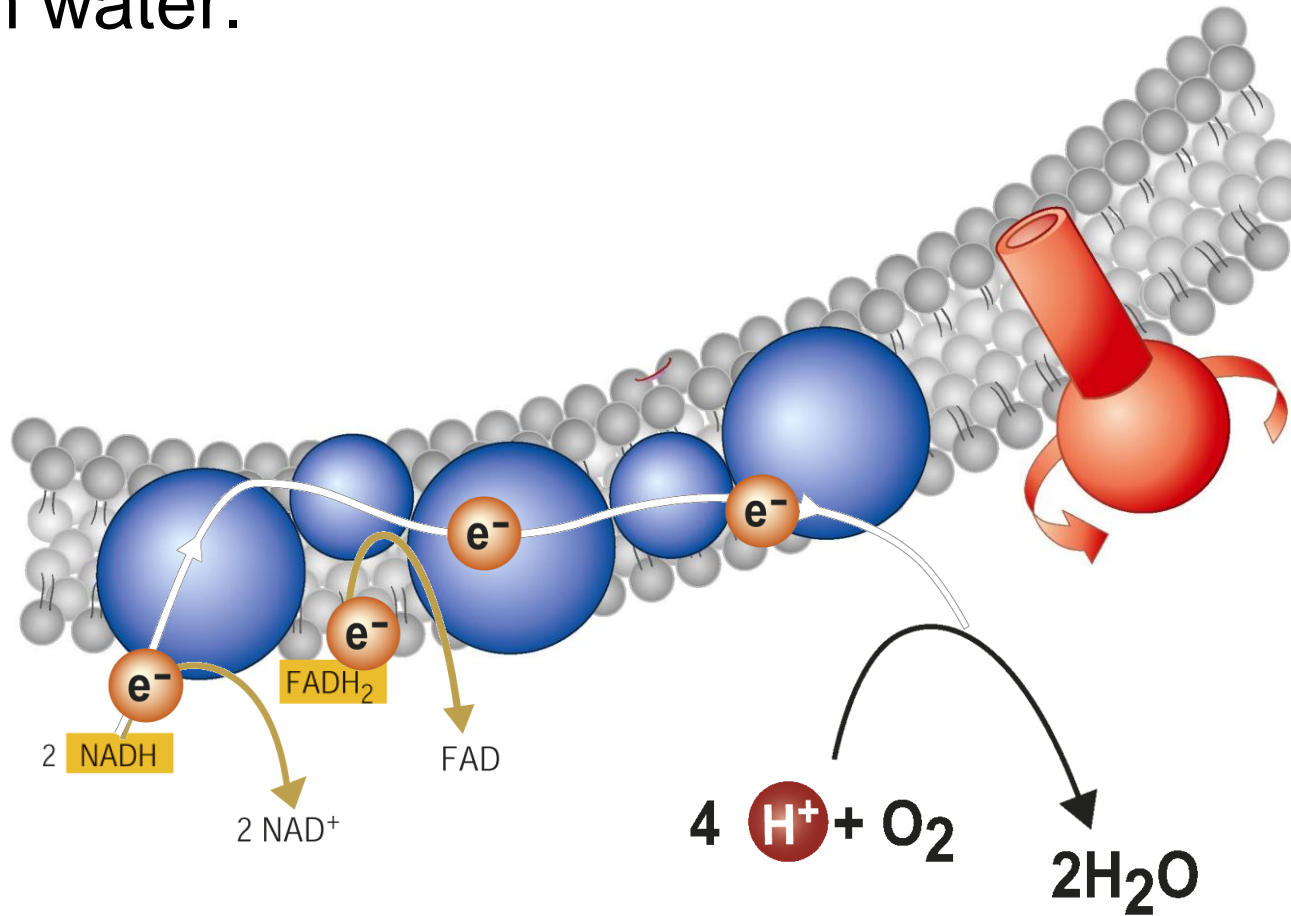

High-energy electrons from NADH and FADH₂ are passed along the electron transport chain from one carrier protein to the next.

9-2 The Krebs Cycle and Electron Transport

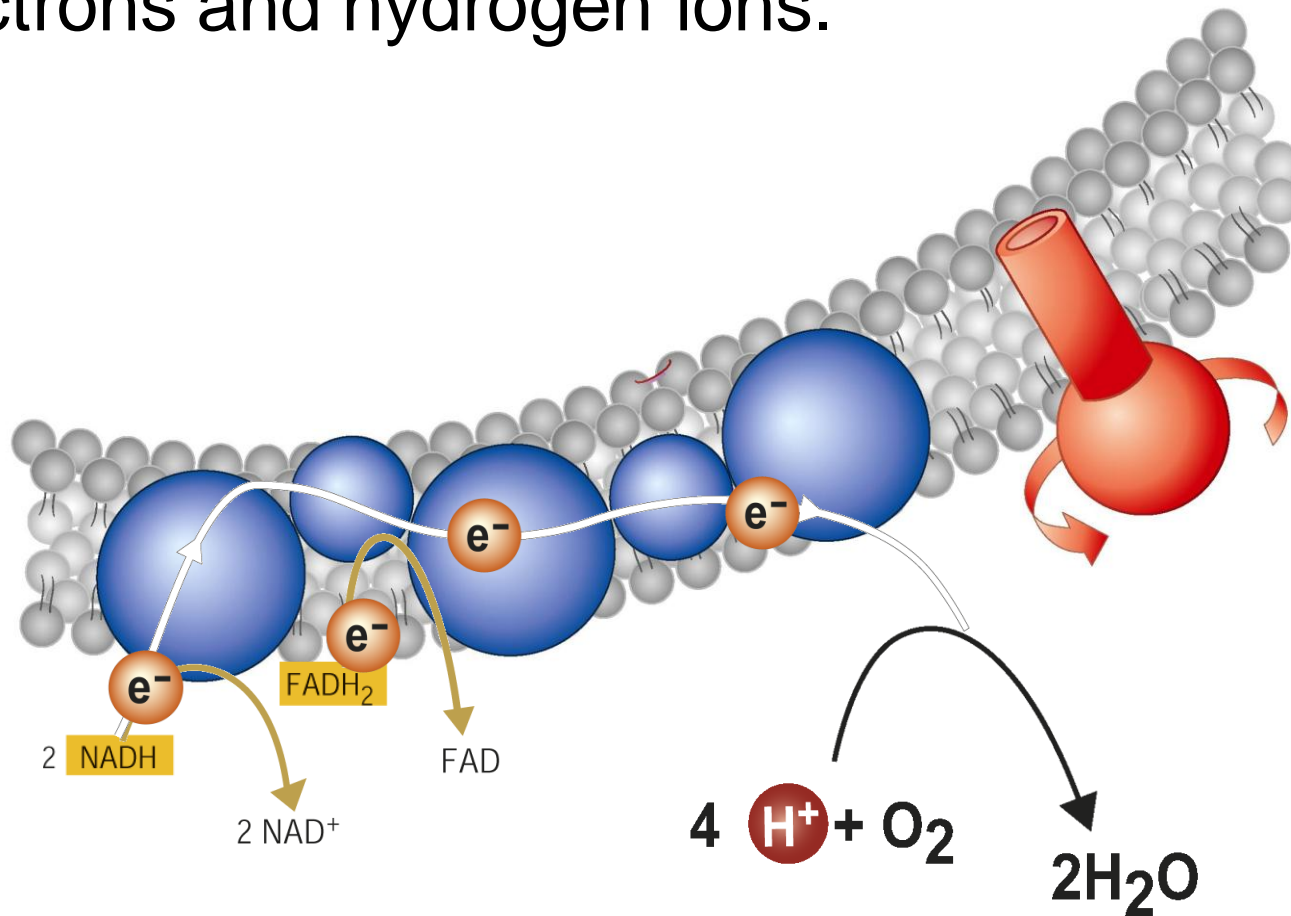

Electron Transport

At the end of the chain, an enzyme combines these electrons with hydrogen ions and oxygen to form water.

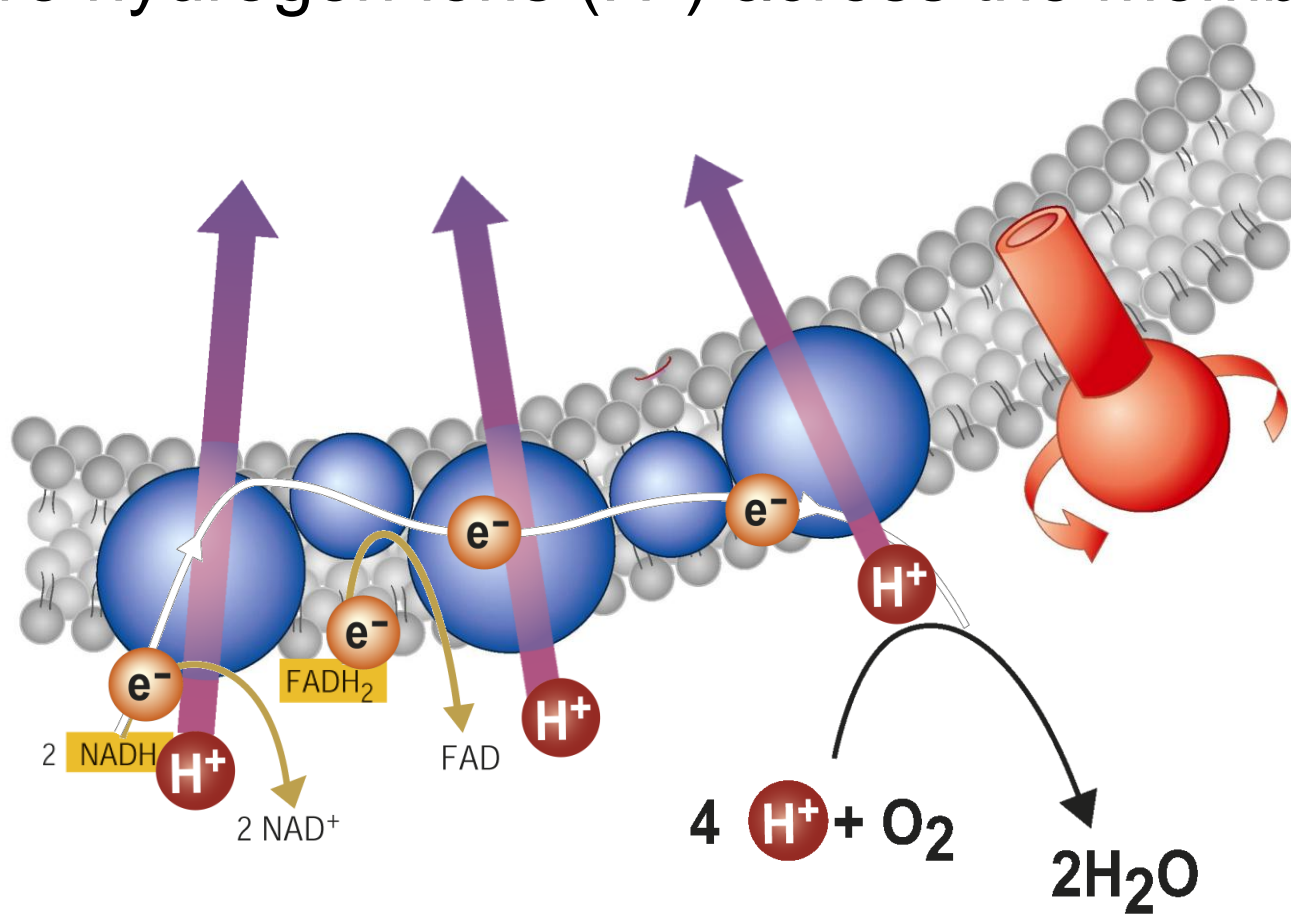

9-2 The Krebs Cycle and Electron Transport Electron Transport

As the final electron acceptor of the electron transport chain, oxygen gets rid of the low-energy electrons and hydrogen ions.

9-2 The Krebs Cycle and Electron Transport Electron Transport

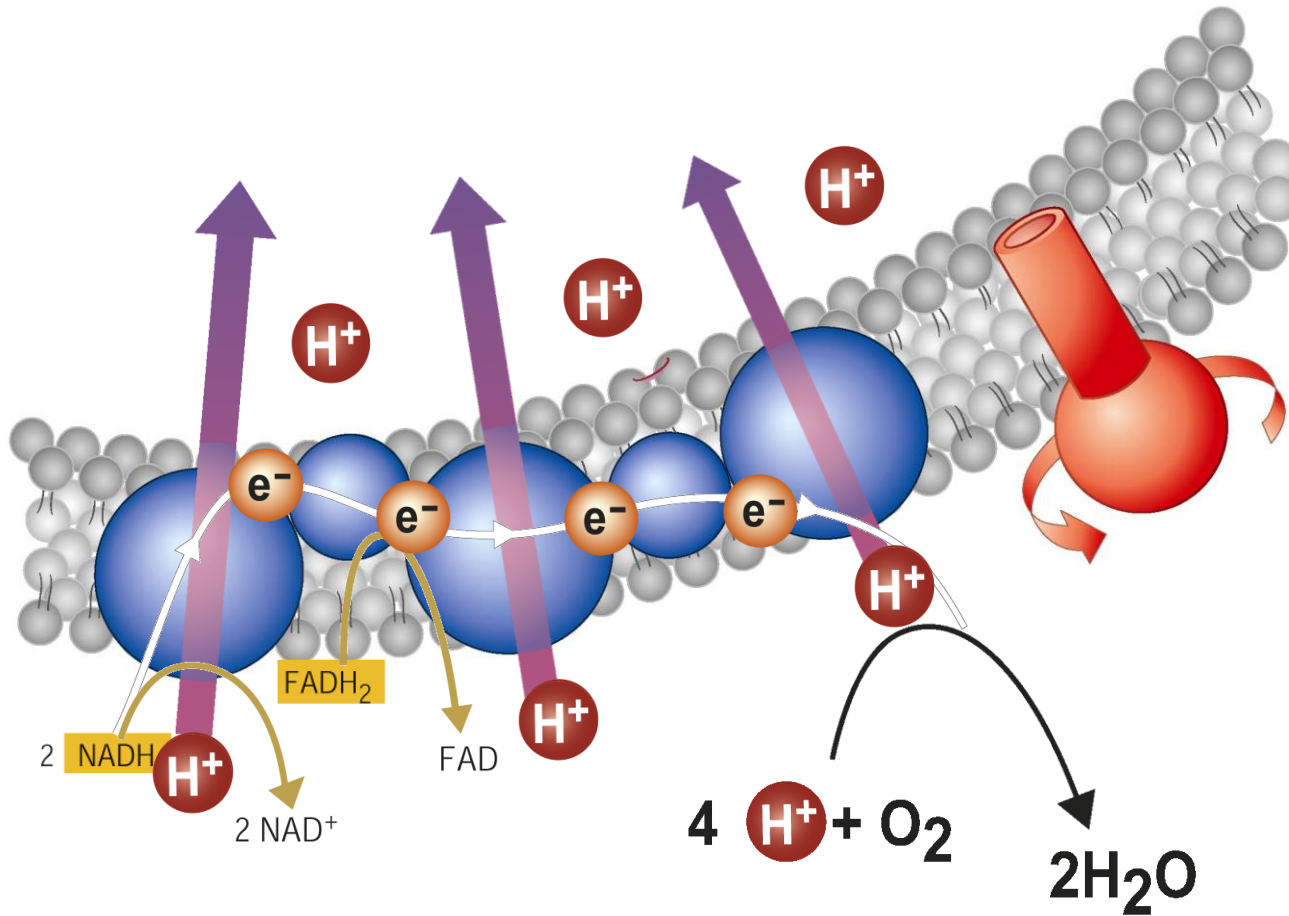

When 2 high-energy electrons move down the electron transport chain, their energy is used to move hydrogen ions (H^+) across the membrane.

9-2 The Krebs Cycle and Electron Transport Electron Transport

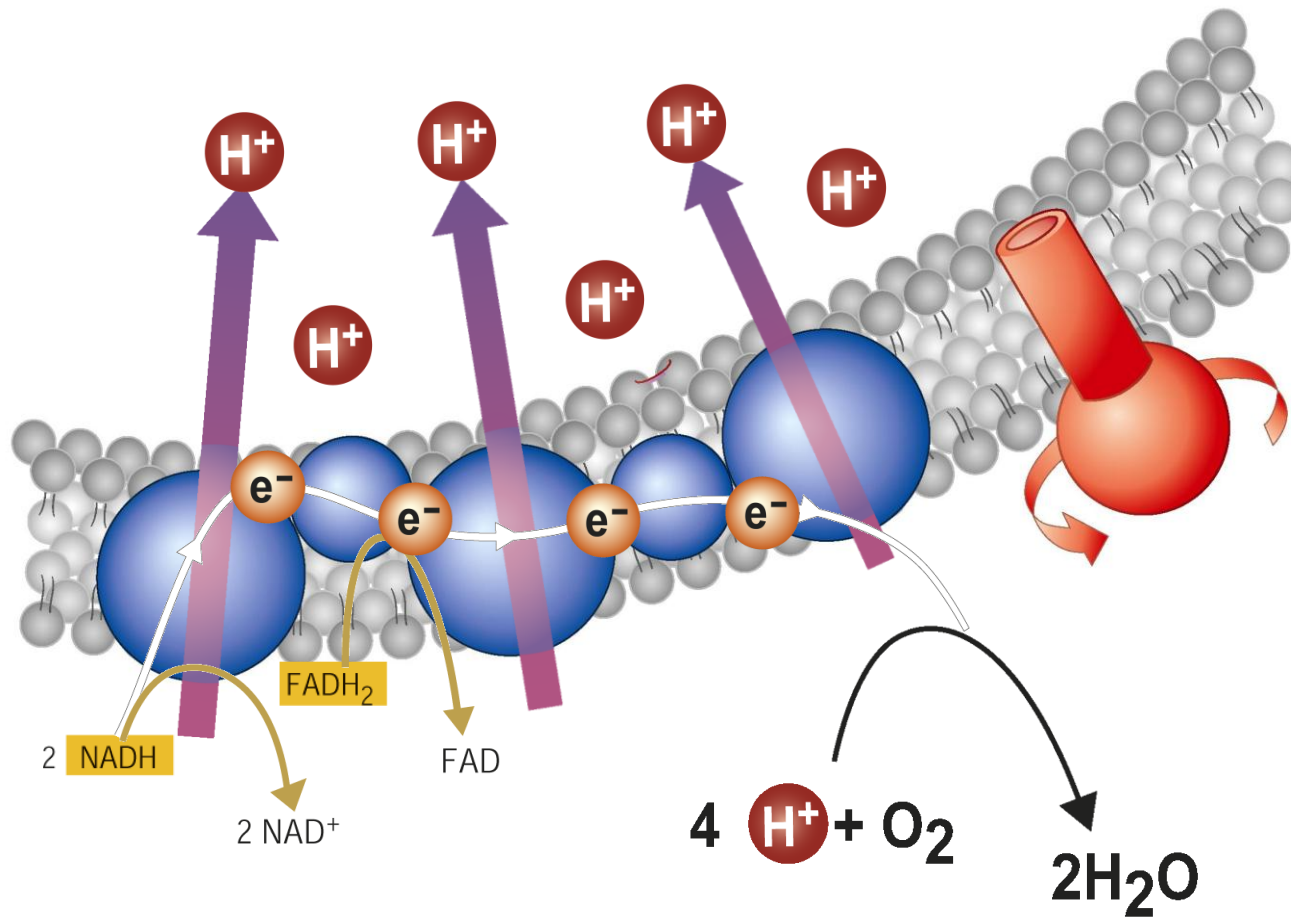

movie
click to start

During electron transport, H^+ ions build up in the intermembrane space, so it is positively charged.

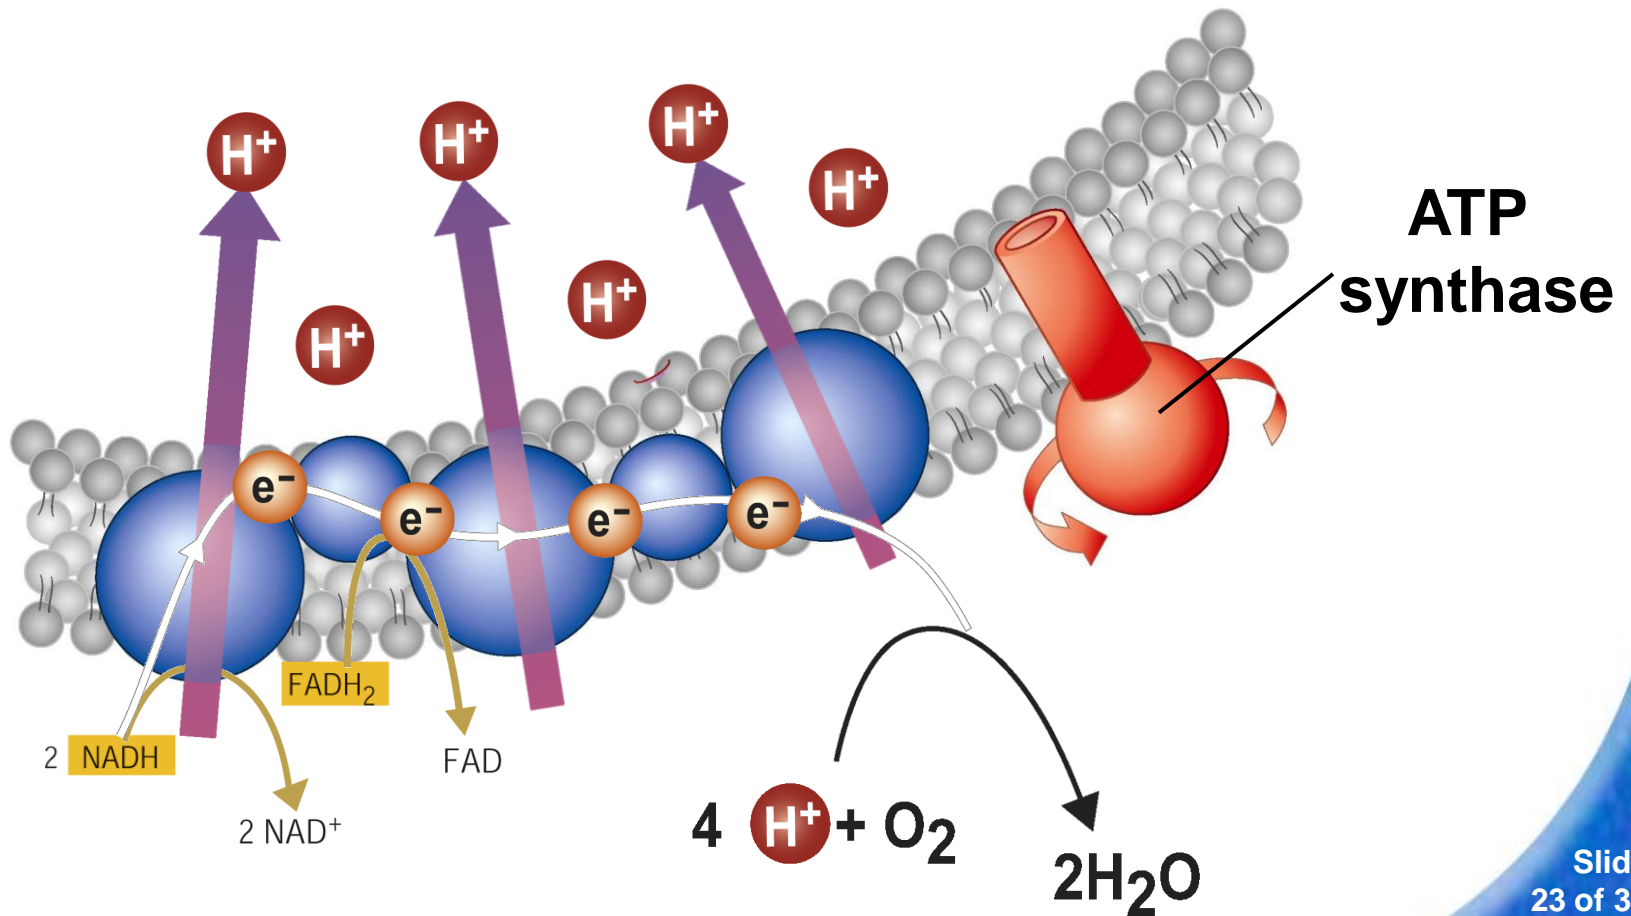

9-2 The Krebs Cycle and Electron Transport Electron Transport

The other side of the membrane, from which those H^+ ions are taken, is now negatively charged.

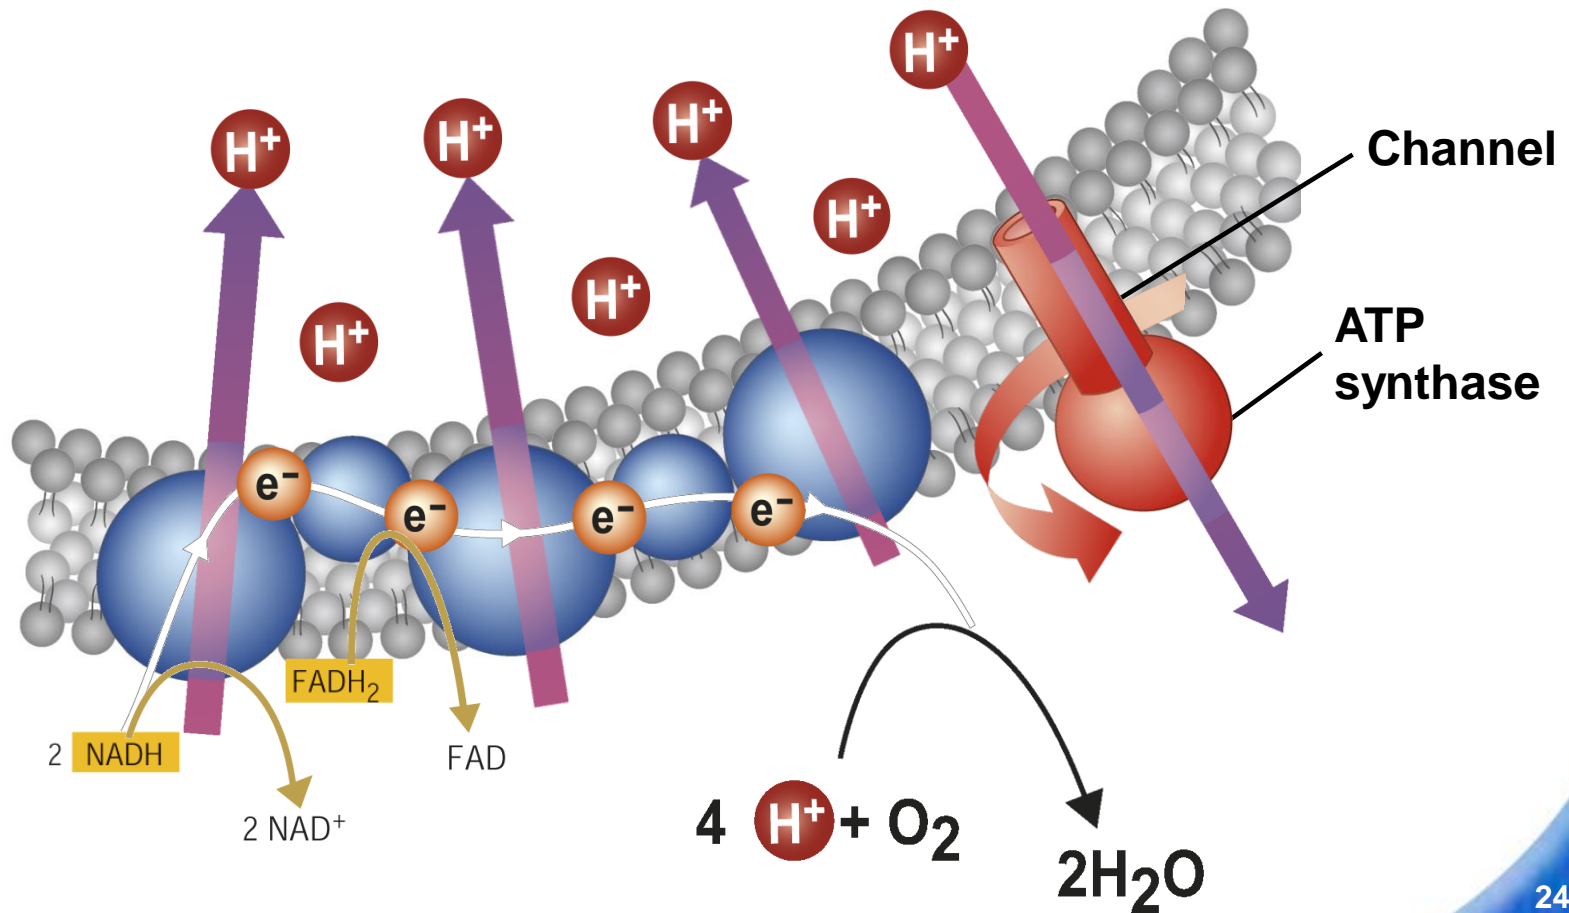

9-2 The Krebs Cycle and \rightarrow Electron Transport Electron Transport

The inner membranes of the mitochondria contain protein spheres called ATP synthases.

9-2 The Krebs Cycle and \rightarrow Electron Transport Electron Transport

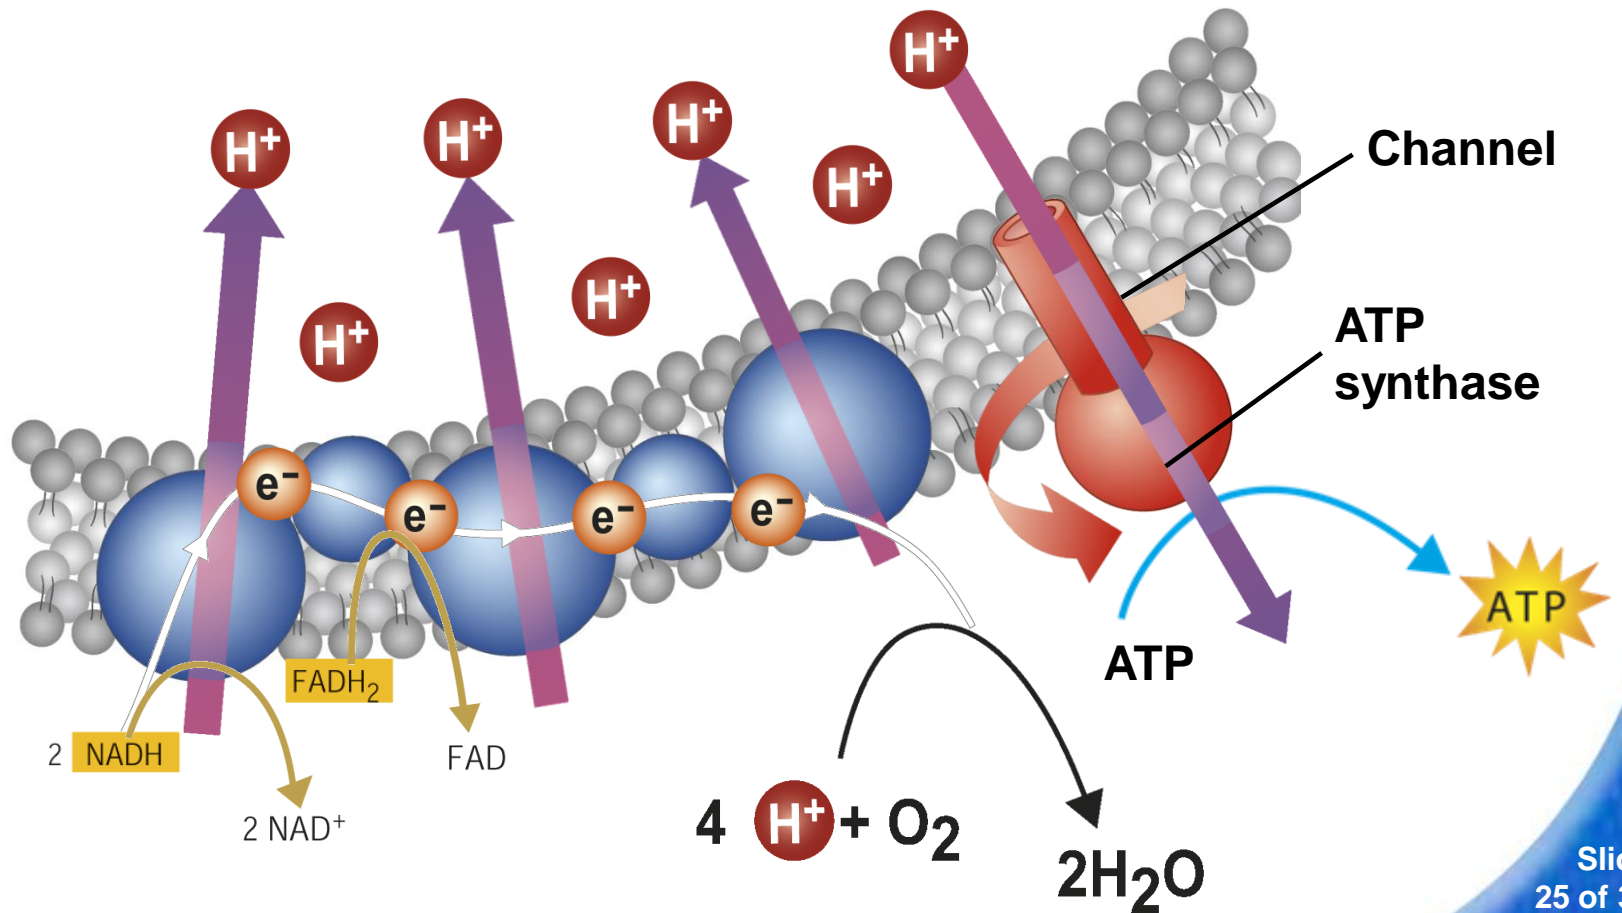

As H^+ ions escape through channels into these proteins, the ATP synthase spins.

9-2 The Krebs Cycle and Electron Transport

Electron Transport

As it rotates, the enzyme grabs a low-energy ADP, attaching a phosphate, forming high-energy ATP.

9-2 The Krebs Cycle and Electron Transport Electron Transport

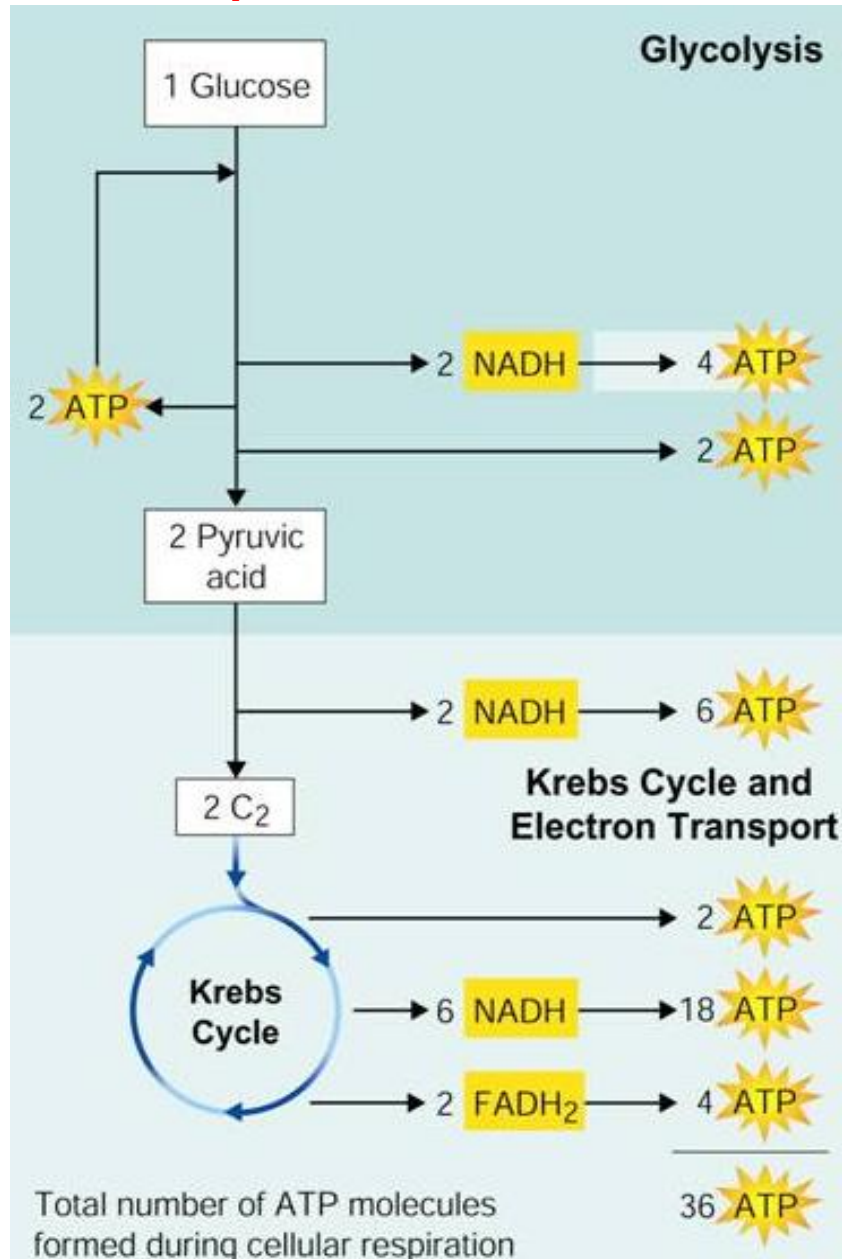

On average, each pair of high-energy electrons that moves down the electron transport chain provides enough energy to produce three molecules of ATP from ADP.

The Totals

Glycolysis produces just 2 ATP molecules per molecule of glucose.

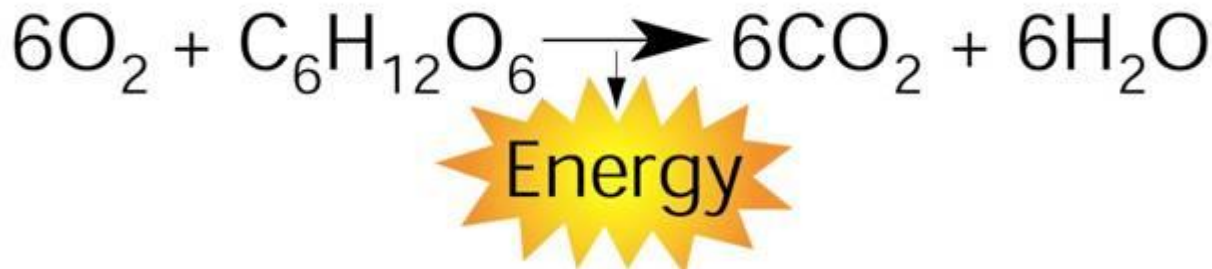

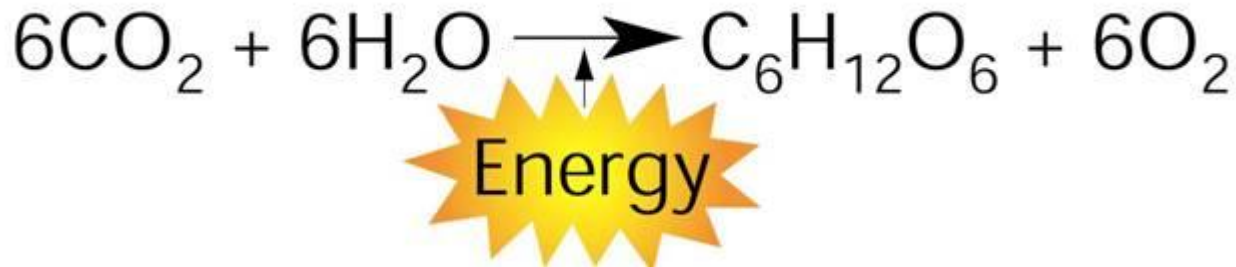

The complete breakdown of glucose through cellular respiration, including glycolysis, results in the production of 36 molecules of ATP.

9-2 The Krebs Cycle and ➡ The Totals Electron Transport

Comparing Photosynthesis and Cellular Respiration

The energy flows in photosynthesis and cellular respiration take place in opposite directions.

On a global level, photosynthesis and cellular respiration are also opposites.

- Photosynthesis removes carbon dioxide from the atmosphere and cellular respiration puts it back.
- Photosynthesis releases oxygen into the atmosphere and cellular respiration uses that oxygen to release energy from food.

Click to Launch:

9-2 Section QUIZ

- 1 The Krebs cycle breaks pyruvic acid down into
- a. oxygen.
 - b. NADH.
 - A** c. carbon dioxide.
 - d. alcohol.

9-2 Section QUIZ

2 What role does the Krebs cycle play in the cell?

a. It breaks down glucose and releases its stored energy.

A b. It releases energy from molecules formed during glycolysis.

c. It combines carbon dioxide and water into high-energy molecules.

d. It breaks down ATP and NADH, releasing stored energy.

9-2 Section QUIZ

3 In eukaryotes, the electron transport chain is located in the

a. cell membrane.

A b. inner mitochondrial membrane.

c. cytoplasm.

d. outer mitochondrial membrane.

9-2 Section QUIZ

4 To generate energy over long periods, the body must use

- a. stored ATP.
- b. lactic acid fermentation.

A c. cellular respiration.

- d. glycolysis.

9-2 Section QUIZ

5 Which statement correctly describes photosynthesis and cellular respiration?

- a. Photosynthesis releases energy, while cellular respiration stores energy.
- b. Photosynthesis and cellular respiration use the same raw materials.

A

c. Cellular respiration releases energy, while photosynthesis stores energy.

- d. Cellular respiration and photosynthesis produce the same products.
